

Capstone Projects

Track choices, rubric, and logistics at a glance

1

YOUR PROJECT

The capstone docs ship two projects, Track A (Procurement, greenfield) and Track B (Release, brownfield). You are not locked to them.

- 1 Build the core project as written in the docs.
- 2 Build the core project and enhance it.
- 3 Build your own idea, as long as it's greenfield or brownfield and meets the rubric.

Whichever you pick has to be a greenfield or brownfield project and check off the rubric boxes. Going off-script raises your risk, so only do it if you're confident your team can deliver something working.

2

HOW TRACKS WORK

Greenfield =
build from scratch

Brownfield =
integrate into
existing code

- You don't have to declare your track upfront. You can switch.
- If you bring your own idea, brainstorm from real FedEx processes or pain points, then shape it into a greenfield or brownfield project that hits the rubric.

3

WHAT GETS GRADED

The rubric is the gate, not which project you chose. Read it early and keep checking against it.

You're graded on six categories. Each gets one of three marks: Pass, Pass with notes, or Needs attention. No percentages, no numeric scores. You need Pass or Pass with notes on all six to earn certification. A single Needs attention triggers facilitator review and a remediation note.

1

Agent functionality and correctness

Runs end-to-end without crashing, outputs match your Pydantic models, decisions carry rationale tied to evidence, handles the test inputs and edge cases, calls the right tools with valid arguments.

2

Spec-driven design quality

OpenSpec proposal.md, tasks.md, design.md (where it's non-trivial), and spec deltas all present, coherent, and matching what you built.

3

Engineering quality

Tests on your tools and decision logic, error handling with fallbacks on every tool call, input/output guardrails, no hardcoded secrets, readable code.

4

RAPID controls

Two controls: ITC.009 (peer review, docs/rapid-peer-review.md) and ITC.004 (Go/No-Go, docs/go-no-go-checklist.md). Both must be done for this category to pass.

5

AI-assisted development practice

A real copilot-instructions.md (not the untouched template), preserved commit history, prompt logs or design notes, visible OpenSpec iteration, and you can point to where you corrected or redirected Copilot.

6

Demonstration and communication

Explain why you made design choices, what you'd do differently with more time, and answer the live debrief question.

Deliver something that works, even if it's simple. Incremental, working delivery beats a large attempt that fails.

Instructors in the room are the final evaluators on whether a self-chosen project counts for the capstone.

4

ENVIRONMENT AND LOGISTICS

VMs have no restrictions. Deploying on the FedEx environment means dealing with its constraints.

You can choose where to deploy your capstone, but the VM is recommended: unlimited access, run MCP servers freely, nothing blocking what you pull down, and cloud or GCP deployment isn't required.

Share code via GitHub (personal or FedEx Enterprise, but FedEx Enterprise might not work on VMs). Working on the shared VM is preferred to avoid access limits.

Demos run locally: one teammate shares screen and runs the app on the VM.

Presentations are recorded and shared with future cohorts.

FedEx managers and leadership will attend to see how projects relate to FedEx.

BOTTOM LINE

Pick a project
you can finish

Use the rubric as
your checklist

Prefer the VM to
reduce scope and friction
